SYMPOSIUM V
SYSTEMATIC, TAXONOMY, ECOLOGY, DIVERSITY OF LAND AND FRESHWATER MOLLUSKS
Preliminary phylogeography of *Lymnaea stagnalis*: are there cryptic species of the great pond snail?

Maxim V. Vinarski\(^1\); Katrin Schniebs\(^2\); Peter Glöer\(^3\); Anna K. Hundsdoerfer\(^2\)

The great pond snail, *Lymnaea stagnalis* (L., 1758), is an aquatic gastropod with a Holarctic distribution. It is usually regarded as a single species with no subspecies (Jackiewicz, 1998; Glöer, 2002), but in the past there was a tendency to recognise several taxa of various rank. Kruglov & Starobogatov (1993) proposed splitting *L. stagnalis* into six distinct species. All works quoted above were based on morphology only. Remigio and Blair (1997) reported that there is a significant genetic divergence between European populations of *L. stagnalis*. Bargues et al. (2001) stressed that geographically separated populations in Europe “show marked divergences”. We investigated the phylogeographic structure of *L. stagnalis* by using sequences taken from specimens corresponding to the morphotypes of *L. stagnalis* s.str. and *L. fragilis* (L., 1758) collected in Europe, Asia Minor, Siberia, and North America. Most specimens are distributed between two sister clades separated by a genetic distance of 0.085. This corresponds to the distances separating some ‘good’ (morphologically and genetically defined) species of lymnaeids, for example, *Radix balthica* (L., 1758) and *R. ampla* (Hartmann, 1821). It is more than twice higher than the genetic distance between lymnaeid subspecies (Vinarski et al., 2012). No conchological or anatomical characters to distinguish between these clades were so far revealed. The two large clades show almost clear geographic pattern of distribution. One of them includes all snails collected in Western and Central Europe apart from a few exceptions, whereas the second one comprises snails living in Ukraine, Western Siberia and Asia Minor. North American specimens of *L. stagnalis* belong to the ‘European’ clade. Specimens from Albania and Italy form a third branch that may indicate one more species, *L. raphidia* (Bourguignat, 1860). Possibly, it is a case of cryptic speciation, when two or three incipient species have still not diverged phenotypically enough to be discovered earlier on the basis of their morphology.
